Doomscroll

Data Dictionary — Lab 1

Problem-domain glossary: each term below is defined the way the project team, users, and other stakeholders use it when discussing the system, independent of how it is implemented.

Term	Definition
User	The person reading on-screen content whose head movement and gaze are tracked, and who configures and controls the application.
Calibration	A short guided activity, performed once per user (and repeated if needed), in which the user looks at a sequence of on-screen points so the system can learn to map that user's head and eye movements to positions on their screen.
Calibration Profile	The record of a specific user's completed calibration, which the system reuses in later sessions so the user does not need to calibrate every time.
Head Pose	The orientation of the user's head at a given moment, describing which way the head is turned, tilted, or nodded.
Gaze Direction	The direction the user's eyes are pointing at a given moment, independent of head pose.
Gaze Point	The specific location on the screen that the system currently estimates the user is looking at, obtained by combining the user's head pose, gaze direction, and calibration profile.
Confidence Score	A measure of how reliable a given reading (of head pose, gaze direction, or gaze point) is judged to be, used to decide whether that reading should be acted upon.
Screen Content	Everything currently visible on the user's screen at a given moment, such as an article, document, or webpage the user is reading.
Important Content	The parts of the screen content that make up the material the user is actually reading or working with, such as body text, headings, code, or images referenced by the surrounding text.
Unimportant Content	The parts of the screen content that are not part of the material the user is reading, such as advertisements, decorative backgrounds, or navigation menus, and which are disregarded when deciding whether to scroll.
Content Boundary	The edge (top, bottom, left, or right) of the important content currently visible on screen, used to judge when the user's gaze has reached the end of what they are reading.
Autoscroll	The system's automatic scrolling of the screen content in response to the user's gaze reaching a content boundary, without the user performing a manual scrolling action.
Manual Scroll	Scrolling performed directly by the user through the mouse, trackpad, or keyboard, as opposed to Autoscroll.
Scroll Direction	The direction in which the screen content is moved when a scroll occurs: up, down, left, or right.
Autoscroll Settings	The set of choices a user makes about how Autoscroll behaves for them, including which scroll directions are enabled, how sensitive triggering is, and how fast scrolling happens.

Term	Definition
Session	A single continuous period during which the user is actively using the application, from when tracking starts to when it is paused or the application is closed.
